WT8046

Synchronous Signal Discriminator with Power Saving Detector and Test Pattern for Green Monitor

NOV. 10, 1995

DESCRIPTION

The WT8046 is a silicon monolithic circuit designed for synchronous signal processing and power saving detection of multi-sync display monitors, which can cope with many kinds of PC's and workstations.

It can be applied to display monitors supporting standard IBM VGA, VESA super VGA and IBM 8514/A video modes. It can also be used in other high-end display monitors supporting non-standard video modes with user-defined horizontal/vertical frequency ranges.

The WT8046 incorporates many functional circuits, including horizontal/vertical frequency discrimination, display mode selection, synchronous pulse polarity power saving detection, and test pattern into this single chip IC.

WT8046 is more convenient for you to shrink the PC board size and to reduce the material and labor cost with fewer components.

FEATURES

- 31K (640 x 480) Test pattern output.
- Accepting two separated H&V synchronous signals with positive/ negative polarity.
- Support VESA VGA (640X480, 640X400, 640X350), VESA SVGA (800X600), European SVGA (800X600), and VESA new SVGA (800X600) .
- Capable of processing horizontal frequency between 25KHZ to 80KHZ.
- Standard IBM video mode control outputs (1024X768, 640X480, 640X400, 640X350).
- Five non-standard horizontal frequency control outputs in predefined frequency range.
- Power saving mode - It can detect the conditions of monitor to decide which one will be selected as following: ON/STANDBY/SUSPEND/OFF mode.
- Fixed polarity outputs on both horizontal and vertical synchronous signals.
- Power supply voltage: DC 5 volts; but for those pins with open-drain structure, such like the mode select control output and frequency discrimination control output pins, can be connected to 12 volts through pull-high resistor.

APPLICATION

- Auto size control for Multi-Sync Display Monitors

APPLICATION DESCRIPTION

DPMS (Display Power Management Signaling) Detection

As per DPMS proposal version 1.0P, revision 0.54P, WT8046 provides Monitor Power Management Detection Circuit for the convenience of monitor designers in designing power saving monitors, or the so called "Green Monitors". Please refer to the table 1 as below for power states defined in the DPMS.

DPMS requires at least 5 seconds delay before transition from ON state to any power saving state, to avoid unintentionally entering a power saving state during display resolution changes and timing mode changes. And it can be done instantaneously, for the transition between any power saving state.

Table 1 Display Power Management Summary

State	Signals			DPMS Compliance Requirement	Power Savings	Recovery Time
	Horizontal	Vertical	Video			
On	Pulses	Pulses	Active	Mandatory	None	Not Applicable
Stand-by	No Pulses	Pulses	Blanked	Optional	Minimal	Short
Suspend	Pulses	No Pulses	Blanked	Mandatory	Substantial	Longer
Off	No Pulses	No Pulses	Blanked	Mandatory	Maximum	System Dependent

* "No-Pulse" represents the frequency of Hsin or Vsin less than or equal to 10Hz, but "Pulses" represents that frequency of Hsin greater than or equal to 10KHz and Vsin greater than or equal to 40Hz

The way WT8046 implements VESA DPMS

As shown on Table 2, WT8046 use PM1 to represent Stand-by State, PM2 as Suspend State and PM3 as OFF State. When H_SYNC / V_SYNC signals transition from ON State to any one of the three power saving states, WT8046 will delay 5.9 seconds to meet the VESA DPMS requirement: the minimum 5 seconds delay to avoid unintentionally entering a power saving state during display resolution and timing mode changes. If during this delay time period, H_SYN and V_SYN signals return to ON State, then all three power management pins (PM1, PM2 and PM3) will remain ON state. If power management state of H_SYNC and V_SYNC prolong for more than 5.9 seconds, then these three power management pins will change to the corresponding states. While changing from any power saving state back to ON State will take about 0.368 second for H_SYNC / VSYNC pulse checking. And transition between any power saving state will be done immediately.

Table 2: The truth table of Power Saving Detector

MODE	Hsin	Vsin	PM1	PM2	PM3
ON	Pulses	Pulses	1	1	1
STAND_BY	No Pulses	Pulses	0	1	1
SUSPEND	Pulses	No Pulses	0	0	1
OFF	No Pulses	No Pulses	0	0	0
OVERRIDE	No Pulses	No Pulses	1	1	1
	Manually PWR ON

Fax: 886-35-770419

OVERRIDE mode:

To initial override, both horizontal and vertical sync signals shall be in the no pulses condition when the display is maintained during the entire time override is required. As soon as pulses are detected on horizontal and vertical sync signal. The display shall enter DPMS operation.

In override mode WT8046 has a 31k (640x480) test pattern output as shown in following.

Test pattern has two CROSS BAR Graphic, which can auto changing by 6 sec Timer counter.

Three power management pins are open drain structure and active low. If you do not need all those three power saving states in your design. You can just short two or three pins of the pins PM1/PM2/PM3. for example, by shorting pin PM1 and pin PM2, you will have only two power saving states, that is OFF and Suspend states, so you have three states total, including ON State. Please refer to Application Circuit 1.

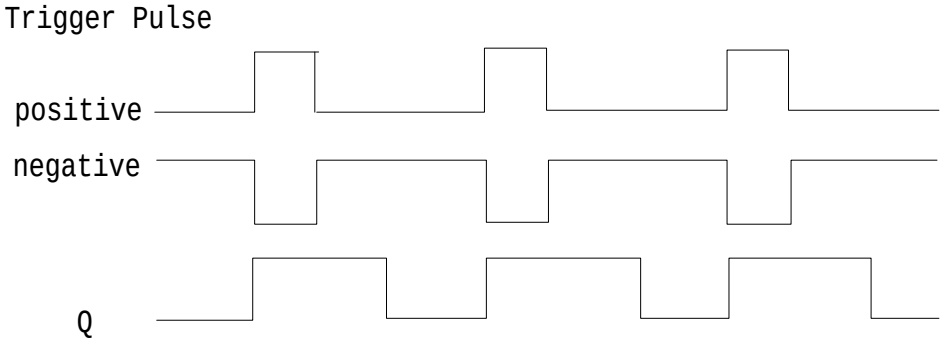
Mono_Stable Circuit

WT8046 includes two sets of Mono_Stable Circuits, one uses H_SYNC as trigger signal, the other uses either H_SYNC or V_SYNC as trigger signal (this for 24 pin and 28 pin packages the trigger signal is fixed to H_SYNC); for N24p4 package, there is no mono-stable circuit.

The Mono_Stable Circuit is triggered by positive edge, no matter H_SYNC or V_SYNC is used as trigger signal. Please refer to the timing chart as below:



The output of Mono_Stable Circuit is open drain structure, and can be pulled up to +12V maximum.

Weltrend Semiconductor, Inc.
2F., No. 24, Industry E. 9th Rd.
Science-Based Industrial Park
Hsin-Chu, Taiwan, R.O.C.
Tel: 886-35-780241
Fax: 886-35-770419

In case of using output pulse of V_MONO_STABLE as voltage source, in order to prevent the problem of slow response time, causing from the low frequency on vertical synchronous signal, WT8046 internally increases the vertical signal frequency to 128 times the original frequency, that is from 50Hz - 120 Hz to 6.4KHz - 15.36KHz. Then WT8046 uses this increased frequency as the input signal of MONO_STABLE, so the leading edge of the signal of the increased frequency will trigger the MONO_STABLE circuit.

An external resistor (Rx) and an external capacitor (Cx) control the timing and accuracy of the circuit. Adjustment of Rx and Cx provides a wide range of output pulse widths from the Q and Q-bar terminals. The delay time from trigger input to output transition is independent of Rx and Cx.

The minimum value of external resistor Rx is 10k ohms. The typical value of external capacitor Cx is 100 pF. The time period (T) for this multi-vibrator can be calculated with the formula: $T \approx 1.1\ Rx \bullet Cx$.

H/V Frequency Divisions and Video Modes

Figure 1 illustrates the typical frequency ranges of H and V sync signals for display monitors. The operating video modes are determined by the H and V frequencies, and occasionally, by their polarities. The typical video modes of display monitors include the IBM VGA, VESA VGA, European VGA/super VGA, VESA super VGA, IBM 8514/A, and XGA.

WT8046 can determine 13 standard video modes (refer to Table 3) according to H and V frequencies and polarities. These standard video modes include the IBM VGA, VESA VGA, VESA super VGA and IBM 8514/A. This provides the users with the capability to adjust the screen size for different modes.

WT8046 pre-sets the discriminating points both on H and V frequencies. The discriminating points for H sync are 33KHz, 36.2KHz, 43.5KHz, 52KHz and 60KHz (for 32 pin). These discriminating points will be able to identify various video modes as shown in Fig. 1. WT8046 also provides the flexibility for users to define these discriminating points through mask option.

Weltrend Semiconductor, Inc.
2F., No. 24, Industry E. 9th Rd.
Science-Based Industrial Park
Hsin-Chu, Taiwan, R.O.C.
Tel: 886-35-780241
Fax: 886-35-770419

The tolerance for H sync frequency discrimination is¡ Ó.1KHz. For instance, the 33KHz discriminating point will be able to distinguish the H sync frequency that is either "less than or equal to" 32.9KHz, or "greater than or equal to" 33.1KHz. There is an ambiguous region between 32.9KHz and 33.1KHz.

WT8046 has two discriminating points, 64Hz and 78Hz, for the V sync signal as shown in Fig.1. The tolerance is ¡ Ó.4Hz. The discrimination results of V sync frequency are used internally for mode selection.

Base on the package consideration, IBM VGA mode and VESA VGA mode (both have same resolution: 640x480, 640x400, 640x350) are decoded on same open Drain structure output pins. In case of these whole six modes decoding is needed, the horizontal frequency discrimination pin F33k or F36.2k must take into consideration. The horizontal frequency of IBM VGA mode is 31.5kHz, and VESA IBM VGA mode is 37.5kHz. Using F33k or F36.2k pin can clearly identify these two standard modes. The decoding circuit is attached on application section for reference.

Graphic Standard	Resolution	Horizontal	Vertical	Polarities
IBM VGA	640X350	31.5kHz	70Hz	+,-
	640X400	31.5kHz	70Hz	-,+

Horizontal Frequency Discriminator

There are horizontal frequency discriminator pins on different type package: 33k, 36.2k (for N24P4 package); 33k, 36.2k, 43.5k (for 24 pin); 33k, 36.2k, 43.5k, 52k (for 28 pin); please refer to table 5 for the logical truth table of these pins. These frequency discriminator pins output can be used for C_S Capacitor Control directly as well as other application.

Signal Hsync	F33k	F36k	F43.5k	F52k	F60k
