# 28V-Capable, ILIm Vbus Accessory Switch 

#### Abstract

General Description The MAX14544/MAX14545 are overcurrent detection switches that can provide power to external accessories while preventing the host device from damage due to faulty overload conditions. These analog switches feature a $270 \mathrm{~m} \Omega$ (typ) on-resistance and operate from $\mathrm{a}+2.3 \mathrm{~V}$ to +5.5 V input voltage range. The selectable current limit of 200 mA or 400 mA makes them ideal for load-switching applications. The MAX14544 has an autoretry feature, whereas the MAX14545 has a latchoff feature. When the switch is off, OUT can withstand 28 V maximum. When the switch is on and a load is connected to the port, a blanking time of 10.5 ms ensures that the transient voltage settles down. After this blanking time, if the voltage across the switch is greater than the $\overline{F L A G}$ assertion voltage, the switch turns off and then a FLAG is issued to the microprocessor. After the retry time, the device recloses for the duration of the blanking time to check if the load current is lower than the limit. The MAX14544 repeats this cycle if the overload condition is present. During the cycle, $\overline{\mathrm{FLAG}}$ remains asserted. The MAX14544 remains on after the overload condition is removed and FLAG deasserts. For the MAX14545, after the blanking time, the switch turns off and then a $\overline{F L A G}$ is issued to the microprocessor. The switch can be turned on again by cycling the power or the EN input. The MAX14544/MAX14545 have additional safety features that include thermal shutdown protection, reversecurrent blocking, and overvoltage protection. The MAX14544/MAX14545 are offered in a space-saving, 8 -pin, $2 \mathrm{~mm} \times 2 \mathrm{~mm}$ TDFN package, and operate over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ extended temperature range.

## Applications

Cell Phones
MP3 Players
PDAs
Digital Cameras
eBook
MID

Typical Operating Circuit appears at end of data sheet.

Features

- 200 mA or 400 mA Selectable Current Limit
- Output Capable of Withstanding +28V
- Reverse-Current Shutdown Protection
- +2.3V to +5.5V Input Operation Range
- Undervoltage Lockout
- Autoretry or Latchoff Option
- Thermal Shutdown Protection
- 0.1 1 A (typ) Shutdown Current
- $5 \mu \mathrm{~s}$ Fast Current-Limit Detect
- 8-Pin TDFN (2mm x 2mm) Package
- $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ Operating Temperature Range

Note 1: Package thermal resistances were obtained using the method described in JEDEC specifications. For detailed information on package thermal considerations, refer to www.maxim-ic.com/thermal-tutorial.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Detailed Description

The MAX14544/MAX14545 are overcurrent detection switches that prevent host devices from being damaged due to faulty load conditions. The switch opens if current exceeds the current limit for longer than the blanking time or if a reverse-current condition is detected. The switch also disconnects if VIN exceeds OVLO, VIN falls below UVLO, thermal shutdown occurs, or EN is driven low. Current limit can be set to either 200 mA or 400 mA . When the switch is open, the output (OUT) can withstand 28 V maximum.
When the switch is on and a load is connected to the port, a blanking time of 10.5 ms ensures that the inrush current settles down. After this blanking time, if the voltage across the switch is greater than the $\overline{F L A G}$ assertion voltage, the part is turned off and issues a FLAG to the microprocessor. After the retry time elapses, the MAX14544 switch is closed for the duration of the blanking time to check if the load current is lower than the limit. Cycle the power or EN input to turn the MAX14545 switch back on.

## Current-Limit Threshold

The MAX14544/MAX14545 ISET logic input sets the desired minimum current-limit threshold to 200 mA or 400mA. Connect ISET low for a 200 mA current limit and high for a 400 mA current limit. If 400 mA is selected as the current limit, the input supply current at shutdown can be reduced by connecting ISET to EN. This is due to the fact that the device consumes the lower supply current in ISET = low mode than in ISET = high mode.

## Reverse-Current Protection

The MAX14544/MAX14545 monitor the reverse current (VOUT to VIN) from exceeding the maximum IDET value. If the reverse-current detection threshold is exceeded, the switch turns off and $\overline{F L A G}$ is asserted without waiting for tBLANK to elapse. This feature prevents excessive reverse currents from flowing through the device.

## FLAG Indicator

The MAX14544/MAX14545 feature a fault output (FLAG). Whenever VIN - Vout > VFA, the MAX14544 asserts FLAG low after the blanking time and keeps it low until the condition is removed. During this time, the switch cycles on and off in the autoretry mode. When the condition is removed, $\overline{F L A G}$ deasserts and the switch turns on (Figure 1). The MAX14545 asserts FLAG low after the blanking time and turns the switch off when FLAG assertion voltage is exceeded (Figure 2).
$\overline{\text { FLAG }}$ is an open-drain output and requires an external pullup resistor. During shutdown (EN is low), the pulldown on FLAG output is released to limit power dissipation. $\overline{\text { FLAG }}$ goes low when one of the following occurs:

1) The temperature exceeds the thermal shutdown temperature, $+150^{\circ} \mathrm{C}$ (typ).
2) The device is in current limit for more than the fault blanking period.
3) The switch is in autoretry.
4) The reverse current limit is exceeded.
5) The input is over the OVLO.

## Autoretry (MAX14544)

When the FLAG assertion voltage is exceeded, the tBLANK timer begins counting (Figure 1). The timer resets if the condition disappears before tBLANK has elapsed. A retry time delay (tRETRY) is started immediately after tBLANK has elapsed and during that time the switch is turned off and $\overline{\text { FLAG }}$ is asserted. At the end of tRETRY, the device is turned on again. If the fault still exists, the cycle is repeated. If the fault is removed, the device stays on and FLAG deasserts.
The autoretry feature saves system power in the case of a continuous overcurrent or short-circuit condition. During tBLANK, when the switch is on, the supply current is at the current limit. During tRETRY, when the switch is off, the current through the switch is zero. Instead of observing the full load current, the device sees the equivalent load current times duty cycle or:
ISUPPLY = ILOAD x tBLANK /(tBLANK + tRETRY)

With a typical tBLANK $=10.5 \mathrm{~ms}$ and typical tRETRY $=$ 661.5 ms , the duty cycle is $1.6 \%$, resulting in a $98.4 \%$ power savings over the switch being on the entire time.

## Latchoff (MAX14545)

When the $\overline{\text { FLAG }}$ assertion voltage is exceeded, the tBLANK timer begins counting. The device turns off after the blanking time. The timer resets if the condition is removed before the end of the blanking time. Reset the device by toggling EN (Figure 2).

## Fault Blanking

The MAX14544/MAX14545 feature a 10.5 ms (typ) fault blanking. Fault blanking allows current-limit faults, including momentary short-circuit faults that occur when plugging a capacitive load, and also ensures that no fault is issued during power-up. When a load transient causes the device to enter current limit, an internal counter starts. If the load-transient fault persists beyond the

# 28V-Capable, ILIM Vbus Accessory Switch 

fault-blanking timeout, $\overline{\text { FLAG }}$ asserts low. $\overline{\text { FLAG }}$ is not asserted when load-transient fault is less than tBLANK. The fault blanking time only applies to forward currentlimit faults.

A reverse current-limit fault, thermal fault, or OVP fault causes $\overline{F L A G}$ to assert immediately and does not wait for the blanking time.

Thermal Shutdown
The MAX14544/MAX14545 have a thermal-shutdown feature to protect the devices from overheating. The device turns off and FLAG goes low immediately (no fault blanking) when the junction temperature exceeds $+150^{\circ} \mathrm{C}$. The MAX14544/MAX14545 turns back on when the device temperature drops approximately $15^{\circ} \mathrm{C}$.

OVLO and UVLO
The MAX14544/MAX14545 feature an overvoltage protection. When IN goes above Vovio ( 6.0 V max), the switch turns off and FLAG goes low immediately with no fault-blanking time. When IN drops below VUVLO ( 1.8 V min ), the switch turns off but $\overline{\mathrm{FLAG}}$ stays high. The MAX14544/MAX14545 turns back on when IN is in the operating range.

## Applications Information

Input Capacitor
To limit the input-voltage drop during momentary output short-circuit conditions, connect a capacitor from IN to GND. A $10 \mu \mathrm{~F}$ ceramic capacitor is adequate for most applications; however, higher capacitor values further reduce the voltage drop at the input and are recommended for lower voltage applications.

## Output Capacitor

Connect a $1 \mu \mathrm{~F}$ ceramic capacitor from OUT to GND. This capacitor helps prevent inductive parasitics from pulling OUT negative during turn-off, thus preventing
the MAX14544/MAX14545 from tripping erroneously. If the load capacitance is too large, then current may not have enough time to charge the capacitance and the device assumes that there is faulty load condition. The maximum capacitive load value that can be driven from OUT is obtained by the following formula:

$$
\mathrm{C}_{\mathrm{MAX}}<\frac{\mathrm{I}_{\text {FWD_MIN }} \times \mathrm{t}_{\text {BLANK_MIN }}}{\mathrm{V}_{\mathrm{IN}}}
$$

Layout and Thermal Dissipation
To optimize the switch response time to output shortcircuit conditions, it is very important to keep all traces as short as possible to reduce the effect of undesirable parasitic inductance. Place input and output capacitors as close as possible to the device. IN and OUT must be connected with short traces to the power bus.
During normal operation, the power dissipation is small and the package temperature change is minimal. If the output is continuously shorted to ground at the maximum supply voltage, the operation of the switches with the autoretry option does not cause problems because the total power dissipated during the short is scaled by the duty cycle:

$$
P_{\text {MAX }}=\frac{\text { VIN_MAX } \times \text { IOUT_MAX } \times t_{\text {BLANK }}}{t_{\text {RETRY }}+t_{\text {BLANK }}}=51.6 \mathrm{~mW}
$$

where VIN_MAX $=5.5 \mathrm{~V}$, IOUT_MAX $=600 \mathrm{~mA}$, tBLANK $=$ 10.5 ms , and tRETRY $=661.5 \mathrm{~ms}$.

Attention must be given to the MAX14545 where the latchoff condition can be manually reset by toggling EN from high to low. If the latchoff time duration is not sufficiently high, it is possible for the device to reach the thermal-shutdown threshold and never be able to turn the device on until it cools down.
